Gene Regulatory Networks Gaussian Bayesian Network Causal Ordering

Causal Gaussian Bayesian Network

 X_j^k is the expression of gene $j \in 1, \dots, p$ in experiment $k \in 1, \dots, N$

$$X_j^k = m_j + \sum_{i \in \mathsf{pa}(j)} W_{i,j} X_i^k + arepsilon_j$$
 with $arepsilon_j \sim \mathcal{N}(\mathbf{0}, \sigma_j^2)$

with $W_{i,j} \neq 0$ if and only if $i \in pa(j)$ and nodes ordered such that that $i \in pa(j) \Rightarrow i < j$ (i.e., $\mathbf{W} = (W_{i,j})$ is upper triangular). Model parameters are $\theta = (\mathbf{W}, \mathbf{m}, \sigma)$.

- Direct causal effects are W
- Total causal effects are $\mathbf{L} = (\mathbf{I} \mathbf{W})^{-1} = \mathbf{I} + \mathbf{W} + \ldots + \mathbf{W}^{p-1}$

$$W_{i,j} = \frac{d}{dx} \mathbb{E}[X_j | X_{-j}, \operatorname{do}(X_i = x)] \quad L_{i,j} = \frac{d}{dx} \mathbb{E}[X_j | \operatorname{do}(X_i = x)]$$

Estimating causal effects from observational data

Some causal information can be recovered from observational data alone...

Intervention-calculus when the DAG is Absent (Maathuis *et al.*, 2009):

- Estimate the equivalence class of the DAG via the PC-algorithm (Kalisch and Bühlmann, 2007)
- Use intervention calculus to estimate bounds for causal effects across equivalence classes, and rank causal effects
- ⇒ Shown to be better able to predict strong causal effects using observational data alone than Lasso and elastic-net

<ロ> <同> <同> < 回> < 回> < 回> < 回</p>

Estimating causal effects from intervention data

Idea: if gene X_1 is regulated by gene X_2 , its expression level after knock-out of X_2 should differ considerably compared to its wild type (steady-state) expression.

Pinna et al. (2010):

- Data: one wild-type (X_j^{wt} for gene j), and one knock-out experiment for each gene (X_jⁱ for gene j under knock-out of gene i)
- Four different deviation matrices calculated, feed-forward edges down-ranked, and causal links ranked in order of absolute value

⇒ winner of the DREAM4 100-gene challenge

Gene Regulatory Networks Gaussian Bayesian Network Causal Ordering

Posterior Causal Ordering

For any given ordering $o = o_1, o_2, ..., o_p$ we assume the full model: $W_{i,j} \neq \forall i < j$ (not suitable for large *p* without some kind of regularization).

Posterior Causal Ordering is defined as:

 $\mathbb{P}(\textbf{\textit{o}}|\text{data}) \propto \mathbb{P}(\text{data}|\hat{\pmb{ heta}}_{\textbf{\textit{o}}}) imes \mathbb{P}(\textbf{\textit{o}})$

where $\hat{\theta}_{o}$ is the MLE of the full model with causal ordering o and $\mathbb{P}(o)$ is a prior distribution.

Causal effect estimates:

$$\hat{\boldsymbol{W}} = \sum_{\boldsymbol{o}} \mathbb{P}(\boldsymbol{o} | \text{data}) \times \hat{\boldsymbol{W}}_{\boldsymbol{o}} \text{ and } \hat{\boldsymbol{L}} = \sum_{\boldsymbol{o}} \mathbb{P}(\boldsymbol{o} | \text{data}) \times \hat{\boldsymbol{L}}_{\boldsymbol{o}}$$

・ロト < 同ト < 目ト < 目ト < 目と のQQ

Gene Regulatory Networks Gaussian Bayesian Network Causal Ordering

log-likelihood: observational data only

We can show that the GBN model is equivalent to $\mathbf{X} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ with

$$\mu = \mathbf{m}\mathbf{L}$$
 and $\mathbf{\Sigma} = \mathbf{L}^T \operatorname{diag}(\sigma^2)\mathbf{L} = \sum_{j \in \mathcal{I}} \sigma_j^2 \mathbf{L}^T \mathbf{e}_j^T \mathbf{e}_j \mathbf{L}$

where \mathbf{e}_i is a *p*-dimensional null row-vector except for its j^{th} term

The log-likelihood of the model can be written as:

$$\ell(\mathbf{m}, \boldsymbol{\sigma}, \mathbf{W}) = \operatorname{Cst} - N \sum_{j} \log(\sigma_{j}) - \frac{1}{2} \sum_{k} \sum_{j} \frac{1}{\sigma_{j}^{2}} (\mathbf{x}_{j}^{k} - \mathbf{x}^{k} \mathbf{W} \mathbf{e}_{j}^{T} - m_{j})^{2}$$
$$= \operatorname{Cst} - N \sum_{j} \log(\sigma_{j}) - \frac{1}{2} \sum_{k} \sum_{j} \frac{1}{\sigma_{j}^{2}} (\mathbf{y}_{j}^{k} - \mathbf{y}^{k} \mathbf{W} \mathbf{e}_{j}^{T})^{2}$$

with $y_i^k = \left(x_i^k - \frac{1}{N}\sum_{k'} x_i^{k'}\right)$

・ロト < 同ト < 目ト < 目ト < 目と のQQ

Gene Regulatory Networks Gaussian Bayesian Network Causal Ordering

log-likelihood: observational data only

Simple analytical analysis gives:

$$m_j = \frac{1}{N} \sum_k (x_j^k - \boldsymbol{x}^k \boldsymbol{W} \boldsymbol{e}_j^T) \quad \sigma_j^2 = \frac{1}{N} \sum_k (y_j^k - \boldsymbol{y}^k \boldsymbol{W} \boldsymbol{e}_j^T)^2$$

and **W** solution of the following linear system, for all (i, j) s.t. $i \in pa_j$:

$$\sum_{i'\in \mathsf{pa}_i} \textit{W}_{i',j} \sum_k y_i^k y_{i'}^k = \sum_k y_i^k y_j^k$$

In the full model, $pa_j = \{i, i < j\}$ we get:

$$\max \ell(\mathbf{m}, \boldsymbol{\sigma}, \mathbf{W}) = \operatorname{Cst} - rac{N}{2} \log \det \left(\sum_{k} y_{i}^{k} y_{j}^{k}
ight)$$

 \Rightarrow obs. data are uninformative for the causal ordering

Maximizing the Likelihood MCMC framework: Mallows Pairwise preferences: Babington-Smith

<□> < => < => < => = = の < ⊙

log-likelihood: observational + intervention data (1)

Consider experiment *k* with intervention on \mathcal{J}_k ($\mathcal{J}_k = \emptyset$ means no intervention), where $\mathcal{K}_j = \{k, j \notin \mathcal{J}_k\}$ and $N_j = |\mathcal{K}_j|$.

The log-likelihood of the model can now be written as:

$$\ell(\mathbf{m}, \boldsymbol{\sigma}, \mathbf{W}) = \operatorname{Cst} - \sum_{j} N_{j} \log(\sigma_{j}) - \frac{1}{2} \sum_{j} \frac{1}{\sigma_{j}^{2}} \sum_{k \in \mathcal{K}_{j}} (x_{j}^{k} - \mathbf{x}^{k} \mathbf{W} \mathbf{e}_{j}^{T} - m_{j})^{2}$$

Then

$$m_j = \frac{1}{N_j} \sum_{k \in \mathcal{K}_j} (x_j^k - \mathbf{x}^k \mathbf{W} \mathbf{e}_j^T)$$

<ロ> <同> <同> < 回> < 回> < 回> < 回</p>

Maximizing the Likelihood MCMC framework: Mallows Pairwise preferences: Babington-Smith

log-likelihood: Observational + intervention data (2)

The log-likelihood of the model can then be rewritten as:

$$\tilde{\ell}(\boldsymbol{\sigma}, \mathbf{W}) = \operatorname{Cst} - \sum_{j} N_{j} \log(\sigma_{j}) - \frac{1}{2} \sum_{j} \frac{1}{\sigma_{j}^{2}} \sum_{k \in \mathcal{K}_{j}} (\mathbf{y}_{j}^{k, j} - \mathbf{y}^{k, j} \mathbf{W} \mathbf{e}_{j}^{\mathsf{T}})^{2}$$

where for (k, j) such that $k \in \mathcal{K}_j$: $\mathbf{y}^{k, j} = \mathbf{x}^k - 1/N_j \sum_{k' \in \mathcal{K}_j} \mathbf{x}^{k'}$

Then W solution of the following linear system:

$$\sum_{i',(i',j)\in\mathcal{E}} W_{i',j} \sum_{k\in\mathcal{K}_j} y_i^{k,j} y_{i'}^{k,j} = \sum_{k\in\mathcal{K}_j} y_i^{k,j} y_j^{k,j} \quad \text{for all } (i,j)\in\mathcal{E}$$

and

i

$$\sigma_j^2 = \frac{1}{N_j} \sum_{k \in \mathcal{K}_j} (\mathbf{y}_j^{k,j} - \mathbf{y}^{k,j} \mathbf{W} \mathbf{e}_j^T)^2$$

 O(0), o⁽¹⁾, o⁽¹⁾, o^(N) is a (dependent) sample of the target distribution.

Maximizing the Likelihood MCMC framework: Mallows Pairwise preferences: Babington-Smith

Mallows' Proposal

Mallows' Ranking Distribution: with parameter $\phi \in]0, 1[$ and reference ordering *r* is defined by

$$\mathbb{P}(\boldsymbol{o};\phi,\boldsymbol{r})=\phi^{d(\boldsymbol{o},\boldsymbol{r})}$$

where d(o, r) counts the number of pairwise disagreements.

Properties:

- mode is in r
- $\phi \rightarrow$ 0 corresponds to a dirac distribution
- $\phi \rightarrow$ 1 corresponds to the uniform distribution
- normalization factor is $1 \times (1 + \phi) \times \ldots \times (1 + \phi + \ldots + \phi^{p-1})$
- sampling in O(p) with the Repeated Insertion Method

<□> < => < => < => = = の < ⊙

Babington-Smith ranking distribution

Pairwise preferences: for any pair of distinct genes (i, j) one can easily compute:

$$\pi_{i,j} = \mathbb{P}(i < j | \mathsf{data}_{i,j}) \propto \mathbb{P}(\mathsf{data}_{i,j} | i < j)$$

$$\pi_{j,i} = \mathbb{P}(j < i | \mathsf{data}_{i,j}) \propto \mathbb{P}(\mathsf{data}_{i,j} | j < i)$$

with $\pi_{i,j} + \pi_{j,i} = 1$.

Idea: use pairwise preferences to obtain an approximated support for $\mathbb{P}(\boldsymbol{o}|\text{data})$ using the Babington-Smith distribution.

$$\mathbb{P}(oldsymbol{o};oldsymbol{\pi}) \propto \prod_{i < j} \pi_{oldsymbol{o}_i,oldsymbol{o}_j}$$

(ex: if $\boldsymbol{o} = (3\ 1\ 2), \ \mathbb{P}(\boldsymbol{o}; \boldsymbol{\pi}) \propto \pi_{3,1}\pi_{3,2}\pi_{1,2})$

Maximizing the Likelihood MCMC framework: Mallows Pairwise preferences: Babington-Smith

Babington-Smith Strategy

Problem: Repeated Insertion Method not applicable for Babington-Smith distribution. MCMC sampling necessary !

Three steps strategy:

- 1) compute pairwise preferences π $\Rightarrow O(p^2)$ but fast since on restricted datasets
- 2) sample from Babington-Smith distribution $\mathbb{P}(\boldsymbol{o}; \pi)$
 - \Rightarrow fast MCMC since likelihood depend only on π
- 3) compute posterior distribution on approximated support \mathcal{O} \Rightarrow retain only the most likely orderings, support size arbitrary

Remarks:

- the strategy is fast, only Step 3 is time consuming
- what if Babington-Smith support differs from real support ?

Simulations DREAM 4 Rosetta

10-genes network challenge

DREAM = Dialogue for Reverse Engineering Assessments and Methods

Data: 5 datasets, each containing 1 wildtype and 10 KO (one for each gene), true network (with feedback loops) known.

Dataset	Pinna	MCMC-Mallows	Babington-Smith
1	0.83 (0.71,0.95)	0.53 (0.35,0.72)	0.60 (0.41,0.79)
2	0.52 (0.35,0.70)	0.52 (0.36,0.68)	0.55 (0.39,0.71)
3	0.82 (0.69,0.94)	0.69 (0.54,0.84)	0.72 (0.56,0.88)
4	0.90 (0.79,1.00)	0.87 (0.76,0.99)	0.90 (0.78,1.00)
5	0.70 (0.53,0.87)	0.81 (0.69,0.93)	0.76 (0.61,0.90)
All	0.73 (0.67,0.80)	0.80 (0.73,0.86)	0.75 (0.68,0.83)

AUC results (with 95% CI) using statistic $|\hat{W}_{i,j}|$

▲ Ξ ▶ ▲ Ξ ▶ Ξ ΙΞ · · · · Q @

Causal ordering:

- observation data only are uninformative for the causal ordering
- we provide likelihood maximization formulas for any given ordering

Statistical inference

- exhaustive search in O(p!) ($p \simeq 10 \text{ max}$)
- MCMC-Mallows works well
- Babington-Smith fast but unreliable

Further work

- extend Babington-Smith to triplet preferences ?
- large *p* with regularization (ex: Ridge) and parallel tempering
- using Fisher information to develop adaptive designs
